In this case, above the fence in the upper estuarine reaches, the hypoxia has reached more than half way up the water column. Nutrient loading and meteorological conditions explain interannual variability of hypoxia in Chesapeake Bay. Eelgrass survival in two contrasting systems: Station Distance from mouth

The results of the spatiotemporal hypoxia models illustrate important similarities and differences between the Severn and South Rivers. It is cost prohibitive to set up continuous monitoring instrumentation over a large region and in multiple spatial dimensions. Input parameters such as distance, Julian week, depth, and concentration dissolved oxygen were first gridded using an inverse distance isotropic scheme to the second power.

A detailed monitoring program in both the spatial and temporal dimensions was begun with, the small-scale physics of these tributaries does not lend itself to these physical forcing mechanisms.
